

Supplementary figures – IMSC 2026

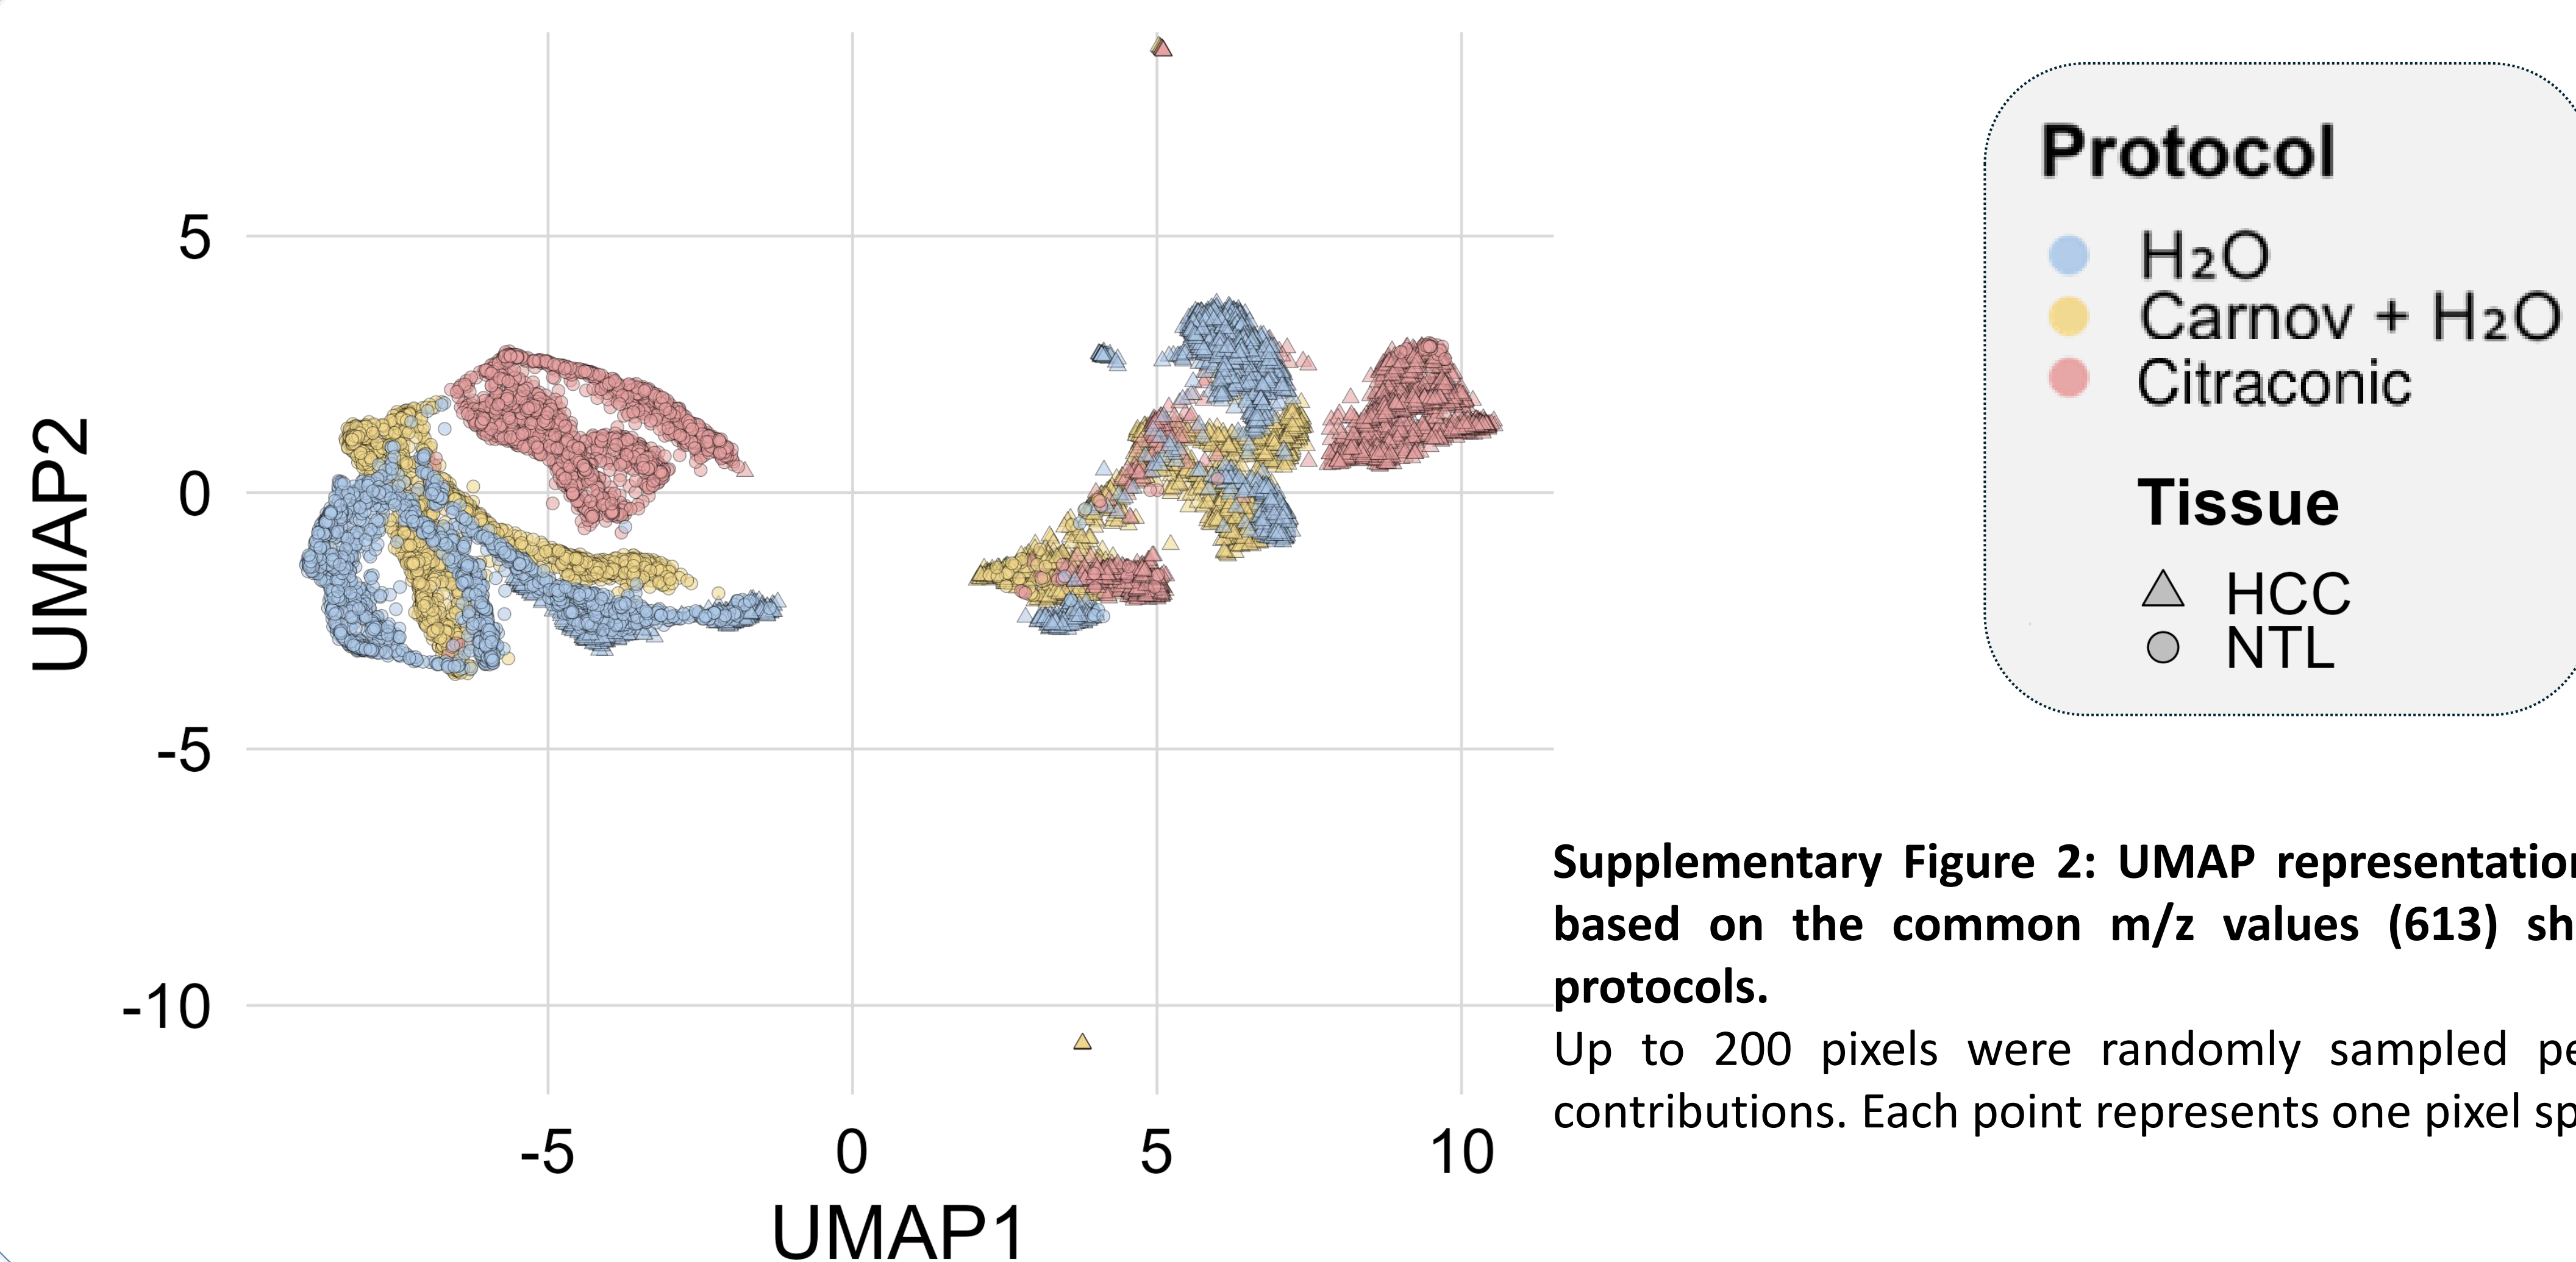

A Multimetric Framework for Standardized Assessment of Mass Spectrometry Imaging Protocols: Hepatocellular Carcinoma as a Proof of Concept

Spectral variability and repeatability

Supplementary Figure 1: Spectral variability and repeatability across selected protocols. Intra-ROI CV was calculated from the 300 most intense m/z features per ROI, whereas Spearman correlations were computed between full harmonized mean ROI spectra. Lower CV and higher correlations indicate better analytical performance.

UMAP of pixel spectra

Supplementary Figure 2: UMAP representation of pixel-level spectra based on the common m/z values (613) shared across the three protocols.

Up to 200 pixels were randomly sampled per ROI to balance ROI contributions. Each point represents one pixel spectrum.

Pssst... I'm open to postdoctoral opportunities!
